

# mEx - An Information Extraction Platform for German Medical Text

Roland Roller, Christoph Alt, Laura Seiffe and He Wang  
Language Technology Lab, DFKI, Berlin, Germany

## Problem/Motivation

Within the clinical routine, text data usually contains additional information beside the structured data (e.g. lab values). This information can be very useful for clinical decision support and end-point prediction. However accessing this information is often difficult as most NLP tools are not specialized on this kind of text. For non-English clinical text, the situation is worse. Only a few tools exist which makes the development cumbersome.

## Solution

We present mEx, an Information Extraction platform for medical text. Some characteristics: **Language:** German - **Domain:** Nephrologie - **Technologie:** Semantic & Syntactic components (see right side) - **Access:** via web & REST interface

## Interface

Input Text

Geht soweit gut bis auf "allgemeine Schlappeheit". Berichtet häufiges Wasserlassen. Etwas Dysurie. Stuhlgang gut. Es gibt keine wesentlichen Ödeme. Gewicht stabil.  
Valcyte angepasst und Medikamente erneut besprochen.  
Sono: Tx-Niere unauffällig, kein Stau, aber perirenale Flüssigkeit.

Semantics Syntax Data successfully retrieved!

Processed Text

1. Geht soweit gut bis auf "allgemeine Schlappeheit". Berichtet häufiges Wasserlassen. Etwas Dysurie. Stuhlgang gut. Es gibt keine wesentlichen Ödeme. Gewicht stabil. Valcyte angepasst und Medikamente erneut besprochen.  
Sono: Tx-Niere unauffällig, kein Stau, aber perirenale Flüssigkeit.

## Information Extraction Components

**Part-of-Speech Tagger** A POS tagger assigns each token a part-of-speech, currently we integrate the Jena Part-of-Speech Tagger (jPOS).

**Dependency Tree Parser** A dependency tree parser infers the syntactic structure of a sentence. mEx integrates a re-trained dependency parser optimized for German clinical text.

**Named Entity Recognition** A NER component detects mentions of pre-defined entities in text, such as drug mentions, body parts or diseases. Our NER component bases on a Bi-LSTM with CRF.

**Factuality Detection** Negations and vague descriptions are a vital part of clinical documentation, as doctors often speculate on the presence of diseases. mEx integrates a modified version of NegEx.

**Relation Detection** A relation describes a particular relationship between concepts or entities, such as a medical condition occurs in a particular body part. Our relation extraction component bases on a CNN.

**Concept Normalization** In medical documentation, different entity mentions can refer to the same concept, e.g. 'pain in the head' and 'cephalgia' both refer to the concept of 'headache'. mEx employs a two-step concept normalization (candidate search and disambiguation) in which mentions are linked against an identical concept within a biomedical ontology.
